Term Structure with Investor Tax Heterogeneity: Application to the Muni Puzzle

Draft coming soon

Abstract: I develop an equilibrium term-structure model in which investors differ in their tax treatment and jointly choose taxable and tax-exempt bonds across maturities under no-short-sale constraints. Top-bracket households receive the largest benefit from tax exemption and therefore anchor short-maturity tax-exempt municipal bond yields. Lower-tax investors value the exemption less, but those for whom duration is more valuable participate in municipals farther out the yield curve, where the relative benefit of bearing duration can offset their tax disadvantage. Endogenous participation therefore makes the tax rate implied by municipal-to-taxable yield ratios vary with maturity, rather than being set by a single marginal investor. This explains the

municipal bond puzzle: the literature benchmarks municipal yields at every maturity against top-bracket households' after-tax taxable yields. These closely match short municipal yields, but long municipal yields substantially exceed them. Without targeting municipal yields, the calibrated model accounts for 83 percent of the 117-basis-point gap at thirty years. Empirically, the pass-through of top-bracket household tax rates to municipal yields declines with maturity, while tax variation affecting lower-tax institutions is increasingly reflected in yields farther out the curve. These opposite maturity gradients support the mechanism and contradict the representative-tax benchmark, in which the top-bracket household's tax rate applies at every maturity.

The Effects of Generative AI on High-Skilled Work: Evidence from Three Field Experiments with Software Developers *with Mert Demirer, Sonia Jaffe, Leon Musolff, Sida Peng, Tobias Salz.* [\[Link to Paper\]](#)

Coverage: *New York Times*, *2025 Economic Report of the President*

Management Science, Forthcoming

Abstract: This study evaluates the effect of generative AI on software developer productivity via randomized controlled trials at Microsoft, Accenture, and an anonymous Fortune 100 company. These field experiments, run by the companies as part of their ordinary course of business, provided a random subset of developers with access to an AI-based coding assistant suggesting intelligent code completions. Though each experiment is noisy and results vary across experiments, when data is combined across three experiments and 4,867 developers, our analysis reveals a 26.08% increase (SE: 10.3%) in completed tasks among developers using the AI tool. Notably, less experienced developers had higher adoption rates and greater productivity gains.

Working Papers

Familiarity in International Equity Investment: Concentrated Value, Pervasive Allocation Bias *with Yinan Qiu.* [\[Link to Paper\]](#)

Abstract: Does familiarity convey information or produce bias? Using 2000–2024 data from 1,663 active U.S. international equity funds and managers' foreign education as a familiarity proxy, we examine both country allocation and stock selection. Funds overweight education-linked countries, yet these sub-portfolios do not outperform. Within familiar countries, the most active quartile of stocks earns a monthly five-factor alpha of 41 basis points, while the remaining holdings earn no significant alpha. The overweight persists after removing top-quartile stocks. Familiarity's value is concentrated, its allocation footprint pervasive: information and bias coexist at margins that country-level averages obscure.

The Shadow in the Shadow: Cheap Bonds and Costly Debt in Chinese Local Government Finance *with Tao Shen, Wei Xiong, Tianqi Zhi.*

Draft available upon request

Abstract: Chinese local government financing vehicles (LGFVs) borrow through publicly traded standard bonds and through nonstandard debt, such as privately negotiated trust loans and leases. Regulators have rationed their standard bond issuance since 2021, and the 2023 debt-resolution program put state backing behind these bonds. When standard bond issuance was restricted, LGFVs with maturing standard bonds shifted to nonstandard debt. After 2023, as standard bond yields fell, the gap between an LGFV's nonstandard rates and its standard bond yields widened by 130 basis points. Standard bond yields also lost most of their link to fundamentals,

barely reflecting local land prices and fiscal strength and not moving when an LGFV defaulted on nonstandard debt. Nonstandard rates still price these local fundamentals, and only they predict LGFV revenue and defaults. The backing made LGFV credit risk look smaller in the standard bond market, but the risk remains, priced in costlier and less transparent nonstandard debt.

Public Debt Resolution and the Relocation of Local Information Rents: Evidence from Bank Wealth-Management Products in China *with Tao Shen, Tianqi Zhi.*

Draft available upon request

Abstract: China's 2023 program to defuse local government debt risk had an unintended cost for small local banks, which compete with national banks in the RMB 30 trillion wealth-management market through local credit. Their products hold three times the portfolio share of local government financing vehicle (LGFV) bonds that national banks' products do, mostly from their home provinces, and these holdings deliver the higher returns and fewer losses that attract return-chasing investors. By moving LGFV risk onto provincial balance sheets, the program compressed credit spreads within and across provinces. The premium on home-province bonds fell by two-thirds, and local banks retreated. The premium largely survived in non-standard debt, negotiated claims with no public price, but only the largest local banks had the scale to move into it. De-risking public bonds relocated the return to local information into opaque claims that require scale, and the smallest banks lost most.

Tradeoff between Segmentation and Asset Fragility – Evidence from Municipal Bond Market

Abstract: In this paper, I document a novel finding of larger asset fragility in the less segmented markets in response to aggregate flow shocks. Empirical results suggest that the less segmented markets have larger correlations with aggregate flow. While the less segmented markets drop less in asset price in response to small outflow, these markets are less liquid and more fragile in response to large aggregate outflow. I then develop a new three-layer demand system with multiple extensions to the original one-layer demand system. Importantly, I include the layer of liquidation order, and propose a new instrument named mandate flow-induced trading (MFIT) in demand estimation. The demand system highlights the arbitrageurs' differential behaviors across markets with heterogeneous levels of segmentation. While the arbitrageurs tend to liquidate first and proportionally liquidate more in the more segmented market in response to flow, they have much larger elasticity in the more segmented market. The numerical results using the new demand system produce the asset price dynamic estimates that are qualitatively and quantitatively consistent with the empirical results.
